

lecture3: probability

probability: the chance an uncertain event will occur. always between 0 and 1.

sample space: all possible outcomes of the experiment. Flipping a coin → head and tail are in sample space

→ random variable assigns a numerical value to each outcome in a sample space.

↳ discrete or continous variables

F(x) = P(X ≤ x) ← cumulative distribution function
↳ expresses the prob. that X does not exceed x.

Probability Density Function: f(x)

→ f(x) > 0 for all x.

→ total area under the PDF curve is equal to 1.

→ the probability that x is between a and b is equal to area under curve bounded by a-b.

Cumulative Density Func. is area under the PDF curve from x=min to x0.

Normal Distribution (Gaussian)

→ bell shaped, symmetrical.

(Mean = Median = Mode)
(μ) → location is based

Spread is determined by σ (standard devi)

z-score: **z = (x - μ) / σ** generally → measurement - mean / standard deviation

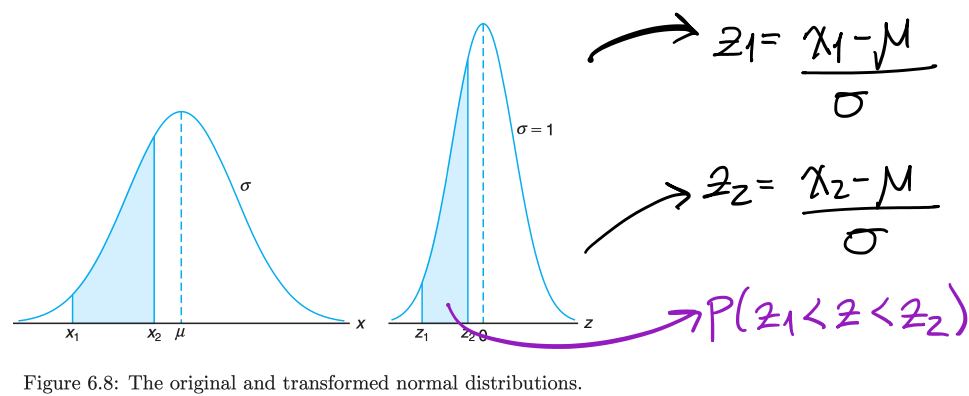

Figure 6.8: The original and transformed normal distributions.

Example

Aluminum sheets used to make beverage cans have thicknesses (in thousandths of an inch) that are normally distributed with mean 10 and standard deviation 1.3.

a) A particular sheet is 10.8 thousandths of an inch thick. Find the z-score.

b) The thickness of a certain sheet has a z-score of -1.7. Find the thickness of the sheet in the original units of thousandths of inches.

F(x) = P(X ≤ x) , **z = (x - μ) / σ**

μ = 10, σ = 1.3

a) **z = (10.8 - 10) / 1.3 = 0.615**

b) **z = -1.7 = (x - 10) / 1.3 → -2.21 = x - 10 → x = 7.79**

Example:

A random variable has a Normal distribution with variance 100. Find its mean if the probability that it will take on a value less than 77.5 is 0.8264.

σ² = 100 → σ = 10

F(x) = P(X < x) ~ P(Z < z)

P(X < 77.5) = 0.8264

then convert to z-score.

P(Z ≤ (77.5 - μ) / 10) = 0.8264

from table 0.94 ~ μ = 68.1

Example:

Example 6.6: Given a normal distribution with μ = 40 and σ = 6, find the value of x that has

(a) 45% of the area to the left and

(b) 14% of the area to the right.

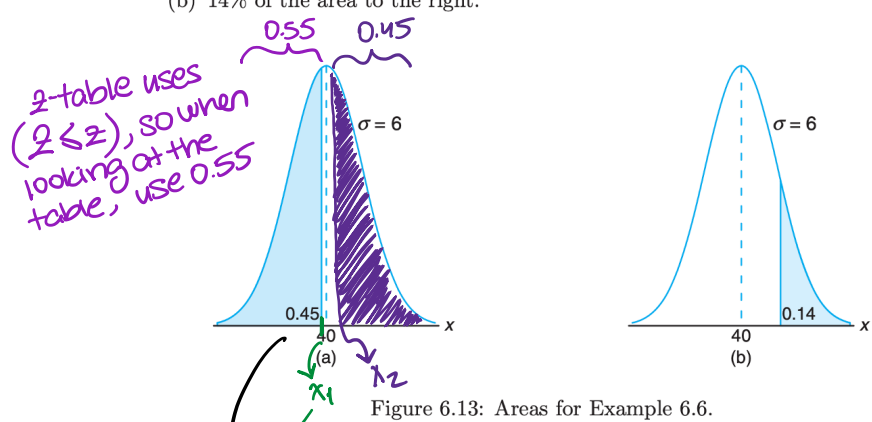

Figure 6.13: Areas for Example 6.6.

P(X < x) = 0.45

find x

① convert to z-score

0.45 = P(Z ≤ (x - 40) / 6) = 0.45 from table

② symmetry → **(40 - x) / 6 = 0.13**

⚠ if z-score is to the left of the mean, it will be negative.
